

Product Engineer Practical Assessment

Indonesia Visa Sponsorship KYC Workflow

Role	Product Engineer
Suggested timebox	4-6 hours maximum
Format	Take-home exercise + follow-up discussion
Reference material	Current Emerhub Indonesia KYC forms for EOR and non-EOR visa sponsorship

What this exercise is testing

We are not testing your knowledge of immigration law. We want to see how you turn a real operational process into simple, reliable software, how you make trade-offs, and how you use modern engineering tools to move quickly without giving up quality.

Background

Emerhub currently collects KYC and due-diligence information for Indonesia visa sponsorship through form- and spreadsheet-based workflows. The process differs depending on whether the applicant is part of an Employer of Record (EOR) engagement or a non-EOR visa sponsorship case.

You will receive the current KYC documents as reference material. Treat them as a description of today's process - not as a perfect product specification. You may simplify, reorganize or improve the workflow where you think it makes sense, as long as you explain your decisions.

Your task

Build a small web-based KYC workflow that could replace the current manual process for an Indonesia visa sponsorship case. The product should support both EOR and non-EOR flows and should be designed so additional countries or process variants could be added later without rebuilding the application from scratch.

Core workflow to support

- Start a KYC case and select the relevant flow (EOR or non-EOR).
- Collect the applicant / employee information required by the current form.
- For EOR cases, collect the foreign employer / company information, beneficial ownership details, employee engagement details and compliance declarations.
- For non-EOR cases, collect applicant details, purpose of stay, planned activities, source-of-wealth information, local address / accommodation details and declarations.

- Allow supporting documents to be uploaded or represented in the workflow.
- Show whether required information is complete or missing.
- Allow an internal reviewer to view the case, add a note, request additional information and update a simple case status.

What we would like you to build

1. A working prototype that demonstrates the main applicant and internal-review flows.
2. Basic data persistence. A lightweight local database, hosted database or similarly pragmatic approach is fine.
3. A simple data model and backend/API layer appropriate to the solution. We are not looking for unnecessary infrastructure.
4. Basic validation and sensible handling of required versus optional information.
5. A clear README or short written note explaining how to run the project and the main decisions you made.

You decide the product details

We intentionally have not specified every screen, field interaction or status. We want to see your product judgment. You do not need to reproduce the current form exactly; simplify the process where it makes sense and explain your decisions.

- Whether EOR and non-EOR should share one adaptive flow or use separate flows.
- How progress, missing information and reviewer feedback should work.
- How declarations, consent and supporting documents should be captured.
- How country-specific and process-specific requirements should be represented so Singapore or another market can be added later.

Please include with your submission

- Link or instructions for running the prototype.
- Source code / repository.
- A short explanation of the architecture and data model.
- What you intentionally did not build within the timebox.
- What you would change before putting the product into production.
- How you used AI tools during the exercise, including what you delegated and what you reviewed yourself.

What is not required

- Perfect visual design.
- Production-ready identity verification, sanctions screening or background-check integrations.
- Real government or immigration-system integrations.
- Perfect legal or regulatory interpretation beyond the supplied reference material.
- A fully production-hardened deployment.

Evaluation

Area	Weight	What we are looking for
Understanding the problem	20%	Can you turn a messy operational process into a coherent product and identify the real user needs?
Product simplicity & UX	20%	Is the workflow clear, practical and appropriately simplified for applicants and internal reviewers?
Engineering quality	20%	Is the solution understandable, maintainable and appropriately tested for the scope of the exercise?
Data & system design	15%	Does the model support both flows and leave a sensible path for new countries / changing requirements?
Pragmatism & scope	15%	Did you make good choices about what to build, what to simplify and what to leave out?
AI-assisted workflow	10%	Did you use AI productively while retaining ownership of correctness, security and design decisions?

Follow-up discussion

In the follow-up interview, we will ask you to walk us through the product and explain the decisions you made. We may explore how you would adapt the solution as Indonesia requirements change, extend it to a second market such as Singapore, prepare it for production, and use AI responsibly. We are interested in your reasoning and trade-offs rather than one correct implementation.

A note on scope

Please keep the exercise within the suggested 4-6 hour timebox. We value clear decisions and a coherent working slice more than feature count. If you run out of time, explain what you would do next rather than extending the exercise significantly.
